Artificial Intelligence in Everyday Life

Source basis: IBM - What Is Artificial Intelligence (AI)?

Artificial intelligence is already used in many everyday tools, often without users thinking about the technology behind them.

Recommendation systems

Streaming services, online stores, and social platforms can use AI to recommend movies, songs, products, or posts. These systems look for patterns in user behavior and use those patterns to predict what a person may find useful or interesting.

Voice assistants and language tools

AI can help computers understand and respond to human language. Voice assistants can convert speech into text, interpret a request, and return an answer. Similar language technology is used in translation, chatbots, transcription, and text summarization.

Navigation and transportation

Navigation applications can analyze maps, traffic information, and route conditions to suggest useful routes. More advanced driving systems can use cameras, sensors, and AI models to detect objects and support driving decisions.

Image recognition

AI systems can identify patterns in images. This can be used for organizing photos, detecting objects, recognizing handwriting, helping inspect products, and supporting some medical-image workflows.

Fraud and security

Banks and online services can use machine learning to look for unusual patterns in transactions or account activity. A suspicious pattern may trigger an additional security check.

Why these systems are not perfect

AI systems learn from data and can make mistakes. A recommendation may be irrelevant, an image may be classified incorrectly, or a language system may misunderstand a request. For important decisions, human judgment and appropriate safeguards remain necessary.
